In this session, GE Vernova experts will show how to pinpoint where your generator, steam turbine, and HRSG systems can capture more power, regain lost performance, and extend asset life.

With power generation, the gas turbine shaft is coupled to the generator shaft, either directly or via a gearbox "direct drive" application. A gearbox is necessary in applications where the manufacturer ...

In this project we are focused primarily on designing a wind turbine specifically for hydrogen production. This effort fits in with H2@Scale through the renewables to hydrogen pathway.

The environmental location factor for wind is based on ASCE 7-16, and it is based on velocity pressure for enclosed, rigid buildings with flat roofs, which is the most widely used building configuration at ...

The potential of P2GSes to provide the capacity of absorbing wind power and carbon reduction is innovatively and thoroughly evaluated in this study. The effectiveness of the proposed ...

Point source carbon capture in fossil fuel-based power production separates CO₂ emissions from a power plant's flue gas or syngas stream to prevent its release into the atmosphere.

The placement of a wind power plant is impacted by factors such as wind conditions, the surrounding terrain, access to electric transmission, and other siting considerations.

As large frame turbines have higher power outputs, they can produce larger amounts of emissions, and must be designed to achieve low emissions of pollutants, such as NO_x. One key to a turbine's fuel-to ...

Based on the design and development of a 30kW low concentration gas catalytic oxidation gas turbine power generation system, the design process of key devices such as catalytic oxidation combustor, ...
